1 **Abstract.** There has been progress in visualization of large graphs re-
2 cently. Still, interacting with a large graph in the browser with the same
3 ease as browsing an online map, inspecting the high level structure and
4 zooming to the lower details, is still an unsolved problem, in our opinion.
5 In this paper we describe MSAGLJS’s approach to two aspects of this
6 problem. Firstly, we give a novel algorithm for edge routing, where the
7 edges do not overlap the nodes. The algorithm does not necessarily cre-
8 ates optimal paths but is efficient and creates visually appealing paths.
 Secondly, to facilitate graph vizualization with DeckGL, we propose a
 new simple and efficient approach to tiling. The aproch guarantees that
 in every view the number of visible entities is not larger than a predefined
 bound.

21 Edge routing

22 The edge routing starts, as in [10], by building a spanner graph, an approximation
23 of the full visibility graph. The spanner, see Fig. 2, is built on a variation of a

24 Yao graph, which was introduced independently by Flinchbaugh and Jones [11]
 25 and Yao [12]. A Yao graph is defined by the set of cones with the apices at
 26 the vertices. The cones have the same angle, usually in the form of $\frac{2\pi}{n}$, where
 27 n is a natural number. This way the cones with the apex at a specific vertex
 28 partition the plane as illustrated in Fig. 1. For each cone at most one edge is
 29 created connecting the cone apex with a vertex inside of the cone.

Fig. 1. Yao graph

31 **Fig. 2.** Spanner graph is built using the idea of Yao graphs. The dashed curves are the
 32 original node boundaries. Each original curve is surrounded by a polygon with some
 33 offset to allow the polyline paths smoothing without intersecting the former.
 34 The edge marked by the circles is created because the top vertex is inside of the cone
 35 and it is the closest among such vertices to the cone apex. The apex of the cone is the
 36 lower vertex of the edge.
 37 MSAGLJS uses cone angle $\frac{\pi}{6}$, so the edges of the spanner can deviate from the optimal
 38 direction by this angle. Therefore the shortest paths on the spanner have length that
 39 is at most the optimal shortest length multiplied by $\frac{1}{\cos(\frac{\pi}{6})} \simeq 1.155$.

43 The approach of [10] first builds a polyline path through the spanner, then
 44 applies some local modifications to shorten and smoothen the path. For short-
 45 ening it tries to shortcut a vertex, as illustrated in Fig 3. To smoothen it fits

Fig. 3. Unsuccessful shortcut

Fig. 4. Fitting a Bezier segment into a polyline corner

Bezier segments into the polyline corners, using the binary search to find the larger fitting segments, see Fig. 4. While analyzing performance of edge routing in MSAGLJS, we noticed that for a graph with more than 10000 edges these heuristics become the major bottleneck.

The reason for this was that we queried if a curve intersects any node of the whole graph. In spite of optimizing these operations with R-Trees [13], about 90% of the edge routing running time was spent on them. In addition, when the naive shortcutting of polyline corners fails the resulting path is not visually appealing, as shown in Fig. 3.

We replace these heuristics with a more precise optimization.

Path optimization

The idea of using the path in a simple polygon optimization is not a new one. The authors of [14] used it, but only for hierarchical layouts, where a simple polygon, \mathcal{P} , containing the path is available. They write: "If \mathcal{P} does not contain holes ... we can apply a standard "funnel" algorithm [15, 16] for finding Euclidean shortest paths in a simple polygon". In general case, for a non-layered layout, they build the visibility graph which is very expensive.

Here we show how to build polygon \mathcal{P} , and create a better path for any layout. Let us describe our method.

We call obstacles \mathcal{O} the set of polygons covering the original nodes, see Fig. 2. Before routing edges we calculate a Constrained Delaunay Triangulation [17] on \mathcal{O} and call it \mathcal{T} . Then for each edge of the graph we proceed with the following steps.

We route a path on the spanner, as illustrated by Fig. 5. Let us call this path \mathcal{L} .

Let \mathcal{S} be the obstacle containing \mathcal{L} 's start point, and \mathcal{E} be the obstacle containing \mathcal{L} 's end point. To obtain \mathcal{P} , let us consider \mathcal{U} , the set of all triangles $t \in \mathcal{T}$ such that either $t \subset \mathcal{S} \cup \mathcal{E}$, or t intersects \mathcal{L} and is not inside of any obstacle. The union of \mathcal{U} gives us \mathcal{P} . The boundary of \mathcal{P} comprises all edges e of the triangles from \mathcal{U} such that e is adjacent to exactly one triangle from \mathcal{U} , see Fig. 6.

To apply the funnel algorithm [15, 16], we need to have a triangulation of \mathcal{P} such

71 **Fig. 5.** Path \mathcal{L} with \mathcal{T} , a fragment.

72 **Fig. 6.** Polygon \mathcal{P} containing \mathcal{L} .

73 **Fig. 7.** New triangulation of \mathcal{P} .

74 **Fig. 8.** Optimized path.

82 that every edge of the triangulation is either a boundary edge of \mathcal{P} , or a diagonal
 83 of \mathcal{P} . In our situation \mathcal{U} usually does not have this property. We create a new
 84 Constrained Delaunay Triangulation of \mathcal{P} , where the set of constrained edges is
 85 the boundary of \mathcal{P} , see Fig. 7.

86 Finally, we apply the funnel algorithm to obtain the path which is the shortest
 87 in the homotopy class of \mathcal{L} , see Fig. 8.

88
 91 The polygon \mathcal{P} is not necessarily simple, as shown in Fig. 9. In this example
 92 the path that we calculate with the funnel algorithm is not the shortest path
 93 inside of \mathcal{P} .

94 Performance and quality comparison

97 In Fig. 10 we compare the paths generated by the old and the new method.
 98 We can see that the paths on the right fragment of the picture have no kinks.
 99 We also know that they are shorter. Arguably, the new method produces better
 100 paths.

112 Our experiments are summarized in Table. 1. We see that the older approach
 113 outperforms the new one on the smaller graphs; those with the number of nodes
 114 under 2000. The new method is faster on the rest of the graphs. We still prefer
 115 to use the new method independently of the graph size since the total slowdown
 116 is insignificant, under a half second in our experiments, but the quality of the
 117 paths is better. On the larger graphs the new method runs faster and produces
 118 better paths, so it is an obvious choice.
